

Cultural Similarity and Team Performance: Evidence from Professional Doubles Tennis

September 4, 2026

Abstract

In increasingly international work environments, cultural similarity may be one dimension along which individuals sort into collaborations. We examine relationship between cultural similarity and team performance where teams are self-sorted using all men's doubles matches at the four Grand Slam tournaments. We measure cultural similarity using shared nationality, shared official language, and linguistic proximity. Culturally similar teams are more likely to win matches. This association has a clear boundary: it disappears in tiebreaks, where teams are closely matched and outcomes are determined over few points. The association strengthens with professional experience but not with partners' experience gap. Finally, although cultural sorting in team formation is substantial, higher-ranked players are not systematically more likely to choose culturally similar partners, suggesting that the performance association is not simply driven by sorting among stronger players.

1 Introduction

Many forms of work increasingly give individuals substantial discretion over whom they collaborate with, including entrepreneurial co-founders choosing business partners, researchers choosing co-authors, consultants assembling project teams, and professionals such as physicians, surgeons, and lawyers forming small working teams. Understanding how individuals form these partnerships is important because the characteristics that shape partner formation may subsequently affect how well collaborators work together.

As organizations and professional networks become increasingly international, these collaborations often bring together individuals from different national, linguistic, and cultural backgrounds. Among the many characteristics that may shape these choices, cultural similarity is one potentially important dimension of team formation process. Individuals may prefer culturally similar collaborators because shared language, norms, or backgrounds can facilitate communication, reduce coordination costs, and make it easier to anticipate one another’s actions. Recent work from Békés and Ottaviano (2025) show that culturally similar players are more likely to pass to one another within elite football teams. This raises a more specific question: “When individuals have substantial discretion over whom they collaborate with, does cultural similarity between the resulting collaborators translate into better performance?”

Answering this question requires a setting in which partner formation and subsequent team performance can both be observed. Professional doubles tennis provides such a real world international setting. Two individuals bilaterally form a partnership and jointly work in a transparent team-production environment: individual contributions during play are directly observable, limiting concerns about unobserved effort and free-riding that can complicate team-performance measures in other settings. Moreover, individuals operate under high-stake economic incentives to maximize joint success.

In this paper, we use professional men’s doubles tennis as an empirical setup to examine 1) the relationship between cultural similarity and team performance, and 2) the extent to which cultural similarity reflects systematic partner sorting.¹ We collect data

¹Partnership formation in professional doubles tennis is inherently multidimensional. Players may sort on several characteristics, including playing ability and experience, strategic complementarity, and institutional or commercial connections such as shared representation by an agency or sponsorship arrangement. Our analysis abstracts from these multiple dimensions of partner selection and focuses on cultural similarity as one potentially consequential dimension of the resulting partnership.

from all men’s doubles matches in Grand Slams between 2018 and 2025. We measure cultural similarity along three complementary dimensions: shared nationality, shared official language, and linguistic proximity. We first examine whether culturally similar teams are more likely to win their matches. We then use tiebreak outcomes to examine a theoretically important boundary condition: whether the association remains visible when the opportunity for teammates to coordinate is sharply compressed. Tiebreaks are played to decide a set once the score reaches 6–6. They are short and closely contested in which relatively few points determine the outcome and teammates have fewer opportunities to communicate and adjust during play.² We find that culturally similar teams are 3.8 to 4.7 percentage points more likely to win Grand Slam matches, with the strongest and most precisely estimated associations observed for the language-based measures. This association, however, has a clear boundary. Cultural similarity is not associated with tiebreak outcomes. Tiebreaks provide a particularly stringent setting in which to examine the performance relevance of coordination: the competing teams have already demonstrated closely matched performance, while the outcome is determined over a short sequence of points that provides relatively little time and opportunity for teammates to communicate, adjust, and coordinate. The potential benefits of cultural similarity may therefore be too small to become visible under these conditions. If culturally similar teams were simply stronger for some persistent reason unrelated to coordination, we would have some reason to expect their advantage to remain visible in tiebreaks. Instead, the association is present when performance is aggregated over the match but not when the outcome is determined over a short, closely contested sequence. We interpret this contrast as evidence of a boundary condition on when cultural similarity can be associated with team performance, rather than as evidence of a universal performance advantage.

We next conduct a specificity robustness check by examining whether the observed association between cultural similarity and match performance is robust across playing surfaces.³ The coefficients are similar and stable across all surfaces, providing no

²Much like a penalty shootout in football, a tennis tiebreak breaks a draw by shifting the match into a rapid-fire point-by-point format where losing a point on your own serve is the psychological equivalent of missing a penalty kick, as the alternating sequence means a single miss often decides the entire set.

³Tennis Grand Slams are contested across three distinct structural profiles: grass at Wimbledon, clay at the French Open, and hardcourts at the Australian and US Opens. These surfaces fundamentally alter communication dynamics.

evidence that the results are driven by a particular playing surface.

We then investigate two distinct roles of professional experience through which cultural similarity may be associated with team performance. First, more experienced players have accumulated greater task-specific knowledge and familiarity with high-level competition. Shared language and cultural background may facilitate communication and help teammates integrate this knowledge into coordinated action. If so, the association between cultural similarity and performance should be stronger among teams with greater professional experience. Second, cultural similarity may facilitate knowledge transfer through communication between experienced and less experienced teammates. If so, the association should strengthen with the within-team experience gap. We find the association between cultural similarity and match performance becomes stronger with team average professional experience, but not more valuable when teammates differ more in experience, suggesting that cultural similarity complements accumulated professional experience in communication and coordination.

Finally, we return to the endogenous team formation stage. We document the extent of cultural sorting in partnerships, examine whether this sorting is particularly pronounced among stronger players. Cultural similarity is substantially more common among observed partnerships than under random matching, confirming that doubles teams are strongly sorted by nationality and language. However, this sorting is not more pronounced among higher-ranked players, and a player's own ranking is, if anything, negatively associated with having a culturally similar partner. We therefore find no evidence for the specific selection explanation in which stronger players systematically choose culturally similar partners. Nevertheless, these descriptive analyses cannot rule out other forms of endogenous partner selection.

Our study relates to three strands of literature. First, it contributes to research on cultural diversity, similarity, and organizational performance. Economic models emphasize that cultural heterogeneity can generate informational and productivity benefits while also creating communication and coordination costs (Lazear, 1999). Organizational research similarly identifies both benefits and costs of cultural diversity, including greater creativity and knowledge variety but also conflict, weaker social integration, and coordination difficulties (Stahl et al., 2010; Harrison and Klein, 2007). Consistent with

these competing forces, evidence on cultural composition and team performance is mixed and context dependent. Much of this literature examines diversity at the workforce or team level. We instead focus on cultural similarity within a small, highly interdependent dyad, where partners must coordinate continuously to produce a common outcome. In such settings, shared language and cultural background may directly facilitate communication and anticipation of a partner’s actions.

Second, our study relates to the literature on endogenous team formation and professional team assembly. This literature emphasizes that teams may emerge through the choices of potential collaborators rather than solely through organizational assignment. Chen and Gong (2018), for example, show in a field experiment that self-selected teams outperform randomly assigned teams, with individuals primarily sorting according to pre-existing social networks. Other experimental studies show that the consequences of self-selection depend on skill complementarities and task characteristics (Büyükboyacı and Robbett, 2019; Fischer et al., 2023), while Foucart, Tan, and Zhao (2025) show how incentives can shape endogenous matching between high- and low-ability individuals. Evidence from professional settings likewise indicates that how temporary teams are assembled can affect coordination and performance (Tonellato et al., 2025). We complement this literature by focusing on cultural similarity as one dimension of endogenous partner choice. We do not seek to model the full matching process: players may also sort on ability, experience, playing style, professional relationships, and commercial considerations. Rather, we examine whether cultural similarity is associated with performance conditional on key observable characteristics such as ranking and professional experience, and whether cultural similarity is systematically reflected in partnership formation.

Third, our study contributes to research on cultural homophily, language, and coordination in collaboration. Language differences can impede information exchange and collaboration in multinational organizations (Marschan-Piekkari et al., 1999; Feely and Harzing, 2003), while linguistic similarity reduces communication frictions in economic interaction more broadly (Melitz and Toubal, 2014). Organizational research on shared mental models further emphasizes the role of common understandings of tasks and teammates in effective coordination (Cannon-Bowers et al., 1993; Klimoski and Mohammed, 1994; Mathieu et al., 2000). Most directly related, Békés and Ottaviano (2025) show

that cultural homophily shapes pairwise collaboration among elite professional football players: culturally similar players are more likely to pass to one another within organizationally constituted teams. Their analysis establishes that culture affects who interacts with whom within an existing team, but does not examine whether such homophilous collaboration translates into aggregate team performance. We take the analysis one step further by asking whether cultural similarity between collaborators is associated with the objective performance of the resulting dyadic partnership, in a setting where continuous real-time coordination is central.

Taken together, these literatures suggest that culture may matter at both the formation and performance margins of collaboration. Our study makes four contributions. First, we extend research on cultural diversity and team performance by shifting attention from aggregate team composition to cultural similarity within a dyadic, highly interdependent team. Second, we extend the literature on endogenous team formation by identifying cultural similarity as a dimension of partner selection and examining whether culturally similar partnerships perform differently, complementing evidence focused on ability, complementarities, incentives, and social networks. Third, we connect research on cultural homophily and pairwise collaboration to objective team performance. Whereas Békés and Ottaviano (2025) examine cultural differences in interaction within established teams, we examine both the formation and performance of the resulting partnership. Fourth, we identify a theoretically informative boundary condition: the association between cultural similarity and performance is not detectable in short, closely contested tiebreaks, while its relationship with professional experience provides additional evidence consistent with a coordination-based interpretation. More broadly, our setting combines substantial discretion over partner formation, directly measurable dyadic cultural similarity, and objectively observed performance.

The remainder of the paper is organized as follows. Section 2 describes the data, measures of cultural similarity, and construction of the empirical sample. Section 3 develops the theoretical framework and hypotheses. Section 4 presents the empirical analysis of cultural similarity and team performance. Section 5 investigates two potential mechanisms related to players' professional experience. Section 6 returns to the formation of partnerships, documenting cultural sorting, examining whether stronger

players are more likely to form culturally similar partnerships, and describing team formation around the Olympic cycles. Section 7 concludes.

2 Data

2.1 Empirical Setting and Sample

Our empirical setting consists of men’s doubles matches from the four Grand Slam tournaments, the Australian Open, Roland Garros, Wimbledon, and the US Open, between 2018 and 2025. The dataset contains 1,864 completed Grand Slam doubles matches and 3,728 team-match observations.⁴

Player information is collected by combining official tournament records from the Association of Tennis Professionals (ATP) and supplementary public sources. Nationality and language information are fully harmonized through a multi-stage validation procedure that resolves inconsistencies arising from spelling variants, accented characters, and historical nationality changes.

Table 1 reports the number of matches in each tournaments by year in Panel A and descriptive statistics at both individual and team level in Panel B.

2.2 Measuring Cultural Similarity

We construct three measures of cultural similarity. The first measure, Same Nationality, equals one if both teammates represent the same country and zero otherwise. The second measure, Same Language, equals one if both teammates share an official national language. The third measure, Language Proximity, is a continuous measure ranging from zero to one that captures the linguistic similarity between teammates’ native languages, with larger values indicating greater linguistic proximity.

These measures reflect increasingly broad notions of cultural similarity. Shared nationality captures common institutional and cultural background. Shared language more directly captures communication potential. Linguistic proximity recognizes that communication costs may also be lower between speakers of closely related languages even

⁴From the initial dataset of 1,921 Grand Slam doubles matches, we exclude retirements and walkovers because these outcomes do not reflect normal competitive performance. We further remove matches with incomplete doubles ranking information that cannot be reliably recovered, resulting in a final sample of 1,864 matches.

Table 1: Observation Breakdown and Descriptive Statistics

Panel A: Matches by Tournament and Year (regression sample)

Tournament	2018	2019	2020	2021	2022	2023	2024	2025	Total
Australian Open	60	62	63	62	59	63	60	61	490
Roland Garros	63	60	62	62	62	61	58	63	491
Wimbledon	61	61	0	60	59	61	61	62	425
US Open	63	60	31	59	62	61	63	59	458
Total	247	243	156	243	242	246	242	245	1,864

Panel B: Descriptive Statistics

Variable	Individual level ($N=7,456$)		Team level ($N=3,728$)	
	Mean	SD	Mean	SD
Doubles ranking	126.02	210.46	126.02	183.51
Years since turning pro	12.59	5.36	11.93	5.17
Age at tournament	31.57	5.19	31.60	4.36
Top-100 singles player (share)	—		8.1%	

Note: Individual-level statistics pool both teammates across all 3,728 team-obs (4 players $\times$ 1,864 matches, minus a small number with missing tenure/DOB). Team-level statistics are the two-teammate average used directly in the regressions (*rank_mean*, *exp_mean*, *age_mean*). Years since turning pro is imputed to 1 for 216 team-obs whose raw tenure is ≤ 0 (rookies who turned pro in or after the tournament year); the team-level mean above reflects this imputation.

when they do not share the same official language.

Table 2: Shares of the Three Cultural Similarity Measures, and Unique Teams by Tournament

Panel A: Cultural Similarity Shares		Panel B: Partnerships by Tournament	
Measure	Share	Tournament	Teams
Same nationality	42.2%	Australian Open	542
Same language	56.0%	Roland Garros	543
Ling. proximity (0–1)	0.568	Wimbledon	487
		US Open	517
		Total	2,089

Note: Panel A reports shares over the 2,089 distinct tournament $\times$ partnership pairings with complete ranking data. Panel B counts the same 2,089 pairings, broken down by tournament.

In our sample, **42.2%** of teams consist of players sharing the same nationality, **56.0%** share an official language, and the mean linguistic proximity is **0.568** on the 0–1 scale.

3 Theory and Hypotheses

3.1 Cultural Similarity and Team Performance

A central concept in the organization literature is the idea of shared mental models. Teams develop shared representations of tasks, roles, priorities, and appropriate responses to different situations. When team members hold sufficiently similar understandings of these dimensions, they can anticipate one another’s actions and coordinate without having to communicate every decision explicitly. Related work on implicit coordination emphasizes that effective teams can rely on shared expectations when responding to recurring situations. Transactive memory systems provide a complementary perspective: through repeated interaction, team members develop an understanding of what their teammates know and how knowledge and responsibilities are distributed within the team.

These perspectives suggest that coordination depends partly on reducing the cognitive and communication costs of joint action. Culture and language can affect these costs. Teammates who share a language may communicate intentions more easily and interpret verbal and non-verbal cues more consistently. Shared nationality may capture additional dimensions of cultural familiarity, including norms, expectations, and common social experiences. More generally, linguistic proximity may reduce communication barriers even when teammates do not share a nationality or an official language.

The implication is not that cultural similarity directly makes a team better. Rather, cultural similarity may make it easier for teammates to combine their individual abilities into effective joint performance. We therefore propose:

Hypothesis 1. *Teams with greater cultural similarity are more like to win matches than culturally dissimilar teams.*

3.2 Tiebreaks as a Boundary Condition

Tiebreaks impose a different temporal and competitive environment in which the opportunity for any coordination advantage to accumulate is substantially reduced.

The coordination benefits associated with cultural similarity are not necessarily equally observable in every part of a match. Coordination is a process that devel-

ops through repeated interaction: teammates communicate, adjust their behavior, learn one another’s tendencies, and build shared expectations. While a full match provides a series of opportunities for this process to operate, a tiebreak substantially compresses these opportunities.⁵ First, tiebreaks are short relative to the match as a whole, leaving less time for a coordination advantage to accumulate. Second, a tiebreak is reached only when the two teams have performed sufficiently similarly to reach a closely contested stage of the set. Its outcome is therefore determined in a setting where relatively small differences in performance can be decisive and where point-level randomness is likely to play a larger role.

These features make the tiebreak a particularly informative boundary condition. If cultural similarity improves team performance partly by facilitating communication in adjusting tactics and coordinating subsequent play, its advantage should be less apparent in a short, closely contested sequence in which there are fewer opportunities for communication and greater scope for point-level randomness. This leads to our second hypothesis:

Hypothesis 2. *The positive association between cultural similarity and team performance is weaker when the opportunity for teammates to coordinate is limited, such as in short, closely contested episodes.*

4 Empirical Analysis

4.1 Match Performance

We test Hypothesis 1 by estimating the association between cultural similarity of the two players within a team and the probability of winning a doubles match. Specifically,

⁵Two distinct tiebreak formats exist in professional tennis. A *standard* tiebreak, played to decide a set once the game score reaches 6–6, is won by the first team to reach 7 points with a margin of at least 2 (so it typically lasts 7–10 points in practice); this format is used in every set of a match, and, at some tournaments, in the final set as well. A *match* or “super” tiebreak, played to 10 points instead of 7, is used at some tournaments as a substitute for a full final set. In our sample, no genuine 10-point match tiebreak is ever used to decide the last set at any of the four Grand Slams. Wimbledon is the only tournament with a non-standard deciding-set format: in 15 of our sample’s matches (7 in 2018, 3 in 2019, 5 in 2021), the last set was instead resolved through extended advantage-set play with no breaker at all, with final scores such as 16–14 and 22–20 – consistent with Wimbledon’s pre-2019 rule of no tiebreak in the deciding set and, for the 2019 and 2021 cases, with its subsequent 12-12-breaker rule simply never being triggered because the set ended before reaching 12-12. At the Australian Open, Roland Garros, and US Open – and in the remaining 79 Wimbledon matches with a completed deciding set – the last set is instead resolved by the same standard 6–6 seven-point breaker used in every other set.

we estimate a Logit model

$$\Pr(W_{ijt} = 1) = f(\beta C_{ijt} + \gamma X_{ijt} + \delta_{ty} + \lambda_r), \quad (1)$$

where W_{ijt} equals one if team i wins match j in tournament-year t , C denotes one of our three measures of cultural similarity: same nationality, same language, and language proximity. X includes three sets of control variables. First, observable own team and opponent team qualities, measured using the average ATP individual doubles ranking of each players.⁶ Lower ranking values indicate stronger players. Second, an indicator for whether either teammate in own team is ranked inside the ATP Top 100 in singles, capturing exceptional individual talent that may not be reflected fully in doubles rankings. Third, professional experience measured as the average number of years since the two teammates turned professional. To allow for diminishing returns, we also include its squared term.

Throughout the analysis we include tournament-by-year fixed effects δ_{ty} and round fixed effects λ_r to absorb common variation across tournaments and stages of competition. Standard errors are clustered at the match level to account for interdependent team-match observations.

⁶The ATP does not publish a persistent, tournament-by-tournament doubles ranking at the pair level: the doubles rankings we scrape are strictly individual, one entry per player, with no team or pairing identifier. The only ATP ranking computed at the pair level is the season-only Doubles Race, used exclusively to seed qualification for the year-end ATP Finals; it resets every calendar year and is defined only for pairs that have accumulated enough joint results together that season, so it does not exist for a large share of our sample – doubles partnerships change frequently across tournaments, and many Grand Slam pairings are new or infrequent. Each player’s own individual ranking, by contrast, is continuously available regardless of current partner, so we use the two teammates’ average individual ranking as the team-quality measure.

Table 3: Match Win — Average Marginal Effects (AME) from Logit

	(1) Same Nationality	(2) Same Language	(3) Lang. Proximity
Cultural similarity	0.0361** (0.0164)	0.0459*** (0.0157)	0.0419*** (0.0157)
Own avg. doubles ranking	−0.0007*** (0.0001)	−0.0007*** (0.0001)	−0.0007*** (0.0001)
Opponent avg. doubles ranking	0.0007*** (0.0001)	0.0007*** (0.0001)	0.0007*** (0.0001)
Top-100 singles player (0,1)	−0.0042 (0.0315)	−0.0030 (0.0315)	−0.0024 (0.0315)
Team avg. professional years	0.0044*** (0.0017)	0.0043** (0.0017)	0.0042** (0.0017)
Team avg. professional years ²	−0.0008*** (0.0002)	−0.0008*** (0.0002)	−0.0008*** (0.0002)
Tournament × year FE	Yes	Yes	Yes
Match round FE	Yes	Yes	Yes
Pseudo- R^2	0.096	0.097	0.097
N	3,728	3,728	3,728

*** $p < 0.01$, ** $p < 0.05$, * $p < 0.10$. Standard errors in parentheses, clustered by match. Unit of observation is team-match (2 team obs. per match); Professional years (Experience) is demeaned at the sample mean (11.93 years)

Table 3 reports average marginal effects (AMEs) estimated in logit models. Across all three specifications, culturally similar teams are significantly more likely to win Grand Slam matches. The estimated effects range from 3.6 to 4.6 percentage points and are strongest when cultural similarity is measured through shared language. Team quality are the dominant predictor of success: stronger own doubles rankings significantly increase the probability of winning, while stronger opponent rankings significantly decrease the probability of winning. Whether having a top 100 singles player in the team does not seem to matter for the match outcome. More experienced teams perform better with diminishing returns.

Alternative specification: randomly assign one team per match as the focal team to be kept in the regression analysis ($N=1,864$). Coefficients are of similar magnitude and slighter weaker significance. Repeated over 10 random seeds: the same-nationality AME averages 0.0466 (range 0.0161–0.0812, significant at the 5% level in 5 of 10 draws), same-language averages 0.0517 (range 0.0230–0.0877, significant in 7 of 10 draws), and language proximity averages 0.0471 (range 0.0156–0.0859, significant in 6 of 10 draws). Similar to Table 3 but slightly different magnitude, as expected from halving the sample and inflating standard errors by roughly $\sqrt{2}$.

These findings provide consistent evidence that cultural similarity is positively associated with team performance after accounting for observable differences in own and opponent quality, experience, and tournament characteristics.

4.2 Testing Tiebreaks as a Boundary Condition

The match-level results establish a positive association between cultural similarity and team performance. We next ask whether this association persists when the opportunity for team coordination is substantially compressed. This provides a boundary condition for the interpretation of the main results. If cultural similarity is associated with performance because shared cultural and communication backgrounds facilitate coordination between teammates, its performance relevance should depend partly on whether teammates have sufficient opportunity to communicate, adjust to one another, and anticipate one another’s actions. The longer the task, the more opportunities teammates have to develop and apply such coordination. By contrast, a tiebreak is a short and highly compressed sequence in which relatively few points determine the outcome.

This setting is particularly informative because a tiebreak is played after the two teams have already demonstrated closely matched performance within the match. The outcome is therefore determined over a much shorter sequence than the match as a whole, leaving less time and opportunity for communication-related coordination advantages to accumulate. At the same time, point-level variation is likely to account for a larger share of the final outcome. Thus, even if cultural similarity is associated with better coordination over the course of a match, its potential performance benefits may be too small to become visible when the competing teams are sufficiently close in performance and the outcome is determined over only a small number of points.

We estimate the same specification used for the match-level analysis, replacing the match-win outcome with an indicator for winning the tiebreak. Table 4 reports the results. Across all three measures of cultural similarity, the estimated associations are substantially smaller than those observed for match outcomes and are not statistically distinguishable from zero. The absence of a detectable association is consistent across shared nationality, shared official language, and linguistic proximity.

The contrast between the two outcomes is informative. If culturally similar teams

were simply stronger for some persistent reason unrelated to coordination, there would be less reason to expect their advantage to disappear precisely when the outcome is compressed into a short sequence. Instead, the association is visible when performance is aggregated over the course of the match but not when the outcome is determined over a brief, closely contested episode. We interpret this pattern as a boundary condition on the performance relevance of cultural similarity: potential coordination benefits may require sufficient time and opportunity to emerge and accumulate, and may therefore be difficult to detect when teams are closely matched and the task provides too little scope for teammates to communicate and adjust.

We estimate the same empirical specification in Equation (1) using tiebreak results as the outcome variable.

Table 4: Tiebreak Win — Average Marginal Effects (AME) from Logit

	(1) Same Nationality	(2) Same Language	(3) Lang. Proximity
Cultural similarity	0.0308 (0.0224)	0.0082 (0.0218)	0.0026 (0.0217)
Own avg. doubles ranking	−0.0003*** (0.0001)	−0.0003*** (0.0001)	−0.0003*** (0.0001)
Opponent avg. doubles ranking	0.0003*** (0.0001)	0.0003*** (0.0001)	0.0003*** (0.0001)
Top-100 singles player (0,1)	−0.0675 (0.0428)	−0.0646 (0.0427)	−0.0644 (0.0427)
Team avg. professional years	0.0027 (0.0022)	0.0023 (0.0021)	0.0022 (0.0021)
Team avg. professional years ²	0.0000 (0.0003)	0.0001 (0.0003)	0.0001 (0.0003)
Tournament × year FE	Yes	Yes	Yes
Round FE	Yes	Yes	Yes
Pseudo- R^2	0.013	0.013	0.013
N	2,354	2,354	2,354

*** $p < 0.01$, ** $p < 0.05$, * $p < 0.10$. Standard errors in parentheses, clustered by match. Unit of observation is team-tiebreak (2 team obs. per tiebreak); standard 7-point tiebreaks only. Same controls and FE as Table 3.

Table 4 reports the results. None of the three measures of cultural similarity is significantly associated with the probability of winning a tiebreak. The estimated coefficients are economically small and statistically indistinguishable from zero. The ranking controls remain highly significant, indicating that the specification continues to capture underlying differences in team quality.

If culturally similar teams were simply stronger for some persistent reason, we would

have some reason to expect that advantage to remain visible in tiebreaks.

Taken together, these findings suggest that the association between cultural similarity and team performance has an important condition: it is more likely to emerge when teammates have sufficient opportunity to coordinate over the course of a task. The positive association with match outcomes, combined with its absence in tiebreaks, is consistent with cultural similarity mattering through coordination processes that can accumulate over time, rather than providing an advantage that operates equally in every episode of team performance. If culturally similar teams were simply stronger for some persistent reason, we would expect that advantage to remain visible in tiebreaks. Instead, the association is present when performance is aggregated over the match but not when the outcome is determined over a short, closely contested sequence. Tiebreaks therefore provide a particularly stringent boundary condition: when two teams are already performing very similarly, the potential performance benefit of cultural similarity may be too small to become visible over a short sequence, in which teammates have limited time and opportunity to communicate, adjust to one another, and translate coordination advantages into the final outcome.

4.3 Robustness check: Testing Tennis-Specific Explanations

One concern is that the observed association reflects strategic characteristics unique to particular playing surfaces rather than general coordination processes. Tennis Grand Slams are contested across three distinct structural profiles: grass at Wimbledon, clay at the French Open, and hardcourts at the Australian and US Opens. These surfaces fundamentally alter ball dynamics, where clay generates high friction that slows the ball and increases bounce height, grass minimizes friction to produce low, rapid trajectories, and hardcourts offer a standardized, intermediate speed and bounce. Consequently, these physical variances dictate distinct communication styles. On fast surface like grass, the rapid pace compresses decision-making windows, forcing partners to rely on pre-packaged tactical scripts and implicit, non-verbal cues because there is no time for mid-rally adjustments. Conversely, on slow surface like clay, longer rallies allow for active, asynchronous verbal feedback during the point, as well as more frequent emotional regulation and strategic recalibration between points to sustain high cognitive

load.

If the observed association were driven by a particular tactical or environmental feature of doubles tennis, we might expect the return to cultural similarity to vary across surfaces, which differ substantially in their playing characteristics. We therefore test whether the association is stable across surfaces by interacting each cultural similarity measure with grass and clay surface, respectively.

Table 5 reports the results. The coefficients are remarkably stable across playing environments, suggesting that the result is not driven by any specific physical environment of the tournament ⁷ The notes below every table have been checked against the underlying estimation code – controls, fixed effects, clustering, sample sizes, and robustness-spec descriptions all match what was actually estimated.

Table 5: Stability across playing surfaces

	(1) Same Nationality		(2) Same Language		(3) Lang. Proximity	
	(a) grass	(b) clay	(a) grass	(b) clay	(a) grass	(b) clay

5 Roles of Professional Experience

In this section we examine the roles of players' professional experience which could shed light on potential mechanisms. Since our data do not directly observe communication or coordination processes, these analyses should be interpreted as mechanism-related heterogeneity tests rather than direct tests of the mechanisms themselves.

⁷As a robustness check, restoring tournament×year FE and estimating C×grass/C×clay jointly (hardcourt as baseline, no separate surface main effect) leaves this conclusion unchanged: both C×grass and C×clay interactions remain small and insignificant (p>0.65) in that specification.

First, players with more years of professional experience are likely to have accumulated greater task-specific knowledge and a better understanding of the demands of high-level competition. When teammates share a language or broader cultural background, communication may make it easier to convey and integrate this experience into joint decision-making, allowing culturally similar teams to translate their individual professional knowledge into coordinated action more effectively. If this channel is important, the association between cultural similarity and performance should be stronger among teams whose members have greater professional experience.

Second, cultural similarity may facilitate knowledge transfer when teammates differ substantially in professional experience. A shared language and cultural background may reduce communication barriers and make it easier for a more experienced player to communicate task-relevant knowledge to a less experienced partner. Under this interpretation, the association between cultural similarity and performance should become stronger as the experience gap within the team increases.

5.1 Average Professional Experience

We first test whether the association between cultural similarity and match performance varies with team average experience. For each team, we calculate the average number of years since the two players turned professional. [Notice that this is not the years the two players have been working together in the same team, but the average individual professional experience of the two players.](#)⁸ We interact this measure with cultural-similarity while retaining the full set of controls and fixed effects from the baseline specification in Equation (1). That is, we estimate the following model

$$\Pr(\text{Win}) = f(\beta_1 C + \beta_2 \text{AvgTeamExp} + \beta_3 (C \times \text{AvgTeamExp}) + \gamma X + \delta_{ty} + \lambda_r) \quad (2)$$

Table 6 reports the results. The interaction between cultural similarity and team average experience is positive for all three measures. For same nationality, however, the interaction is very small and statistically insignificant (0.0008, p=0.809). For the two language-based measures, the interaction is positive and statistically significant: 0.0069

⁸In tennis, partnership can change relatively often. Players may team up with different partners in different tournaments. Calculate how many teams and the share in total have repeated partnership during the sample period and how many unique team appearance.

for shared language ($p=0.032$) and 0.0068 for linguistic proximity ($p=0.034$). Thus, the association between language-related cultural similarity and match performance becomes stronger as team members have more professional experience on average.

Table 6: Team Average Experience

	(1) Same Nationality	(2) Same Language	(3) Lang. Proximity
Cultural similarity (C)	0.0361** (0.0164)	0.0433*** (0.0157)	0.0392** (0.0156)
$C \times \text{exp_mean_dm}$	0.0008 (0.0033)	0.0069** (0.0032)	0.0068** (0.0032)
exp_mean_dm (main)	0.0041* (0.0023)	0.0002 (0.0025)	0.0002 (0.0025)
Controls	Yes	Yes	Yes
Tournament $\times$ year FE	Yes	Yes	Yes
Round FE	Yes	Yes	Yes
Pseudo- R^2	0.096	0.098	0.097
N	3,728	3,728	3,728

*** $p < 0.01$, ** $p < 0.05$, * $p < 0.10$. Standard errors in parentheses, clustered by match. *exp_mean_dm* is demeaned at the sample mean (11.93 years, SD 5.17), so the Culture (C) row is the AME at mean team experience.

The result is robust to allowing the interaction to vary nonlinearly with experience. When we additionally include the interaction between cultural similarity and squared demeaned experience, the quadratic interactions are small and statistically insignificant for all three measures ($p > 0.50$), while the linear interactions for shared language and linguistic proximity remain positive and statistically significant.

This pattern is consistent with a mechanism based on accumulated professional experience and the development of effective coordination. More experienced players may be more able to anticipate teammates' actions and establish efficient communication routines. Cultural and linguistic similarity may make these coordination processes more effective, so that their association with performance becomes stronger among more experienced teams. The fact that the result is concentrated in the language-based measures is particularly consistent with a communication-based interpretation.

Importantly, our measure captures players' individual professional experience, rather than the number of matches a particular pair has played together. We therefore do not directly observe the development of pair-specific shared mental models or communication routines. The evidence should consequently be interpreted as consistent with, rather than establishing, a process in which professional experience strengthens the per-

formance relevance of cultural and linguistic similarity.

5.2 Experience Gaps within the Team

On the other hand, shared language becomes especially valuable when teammates differ substantially in expertise because communication and knowledge transfer become more demanding. Large experience gaps imply asymmetric knowledge, asymmetric decision authority, coaching/mentoring, and more need to transfer tacit knowledge. That is exactly where shared language may matter most. The experience-gap analysis asks whether cultural similarity is particularly valuable when teammates differ in professional experience, conditional on the team’s overall competitive strength and average professional experience. That is, among teams with comparable overall strength and comparable average professional experience, does cultural similarity become particularly valuable when the two teammates differ more in professional experience?

The estimating equation becomes

$$\text{Pr}(\text{Win}) = f(\beta_1 C + \beta_2 \text{TeamExpGap} + \beta_3 (C \times \text{TeamExpGap}) + \gamma X + \delta_{ty} + \lambda_r) \quad (3)$$

The second mechanism makes a different prediction. Cultural similarity may matter particularly when teammates have different levels of professional experience. An experienced player may possess greater knowledge of the demands of elite doubles competition, while an inexperienced teammate may need to learn unfamiliar routines and expectations. Under this knowledge-transfer interpretation, a common cultural and linguistic background could facilitate communication between teammates with different levels of experience. The value of cultural similarity should therefore increase with the experience gap within the team, rather than with the average experience of the two players.

We test this prediction using the absolute difference between the two teammates’ years since turning professional, ExperienceGap=. We interact this measure with each cultural-similarity measure and additionally control for team average experience and its quadratic term. The experience gap is demeaned at its sample mean of 5.50 years, so the cultural-similarity coefficient is evaluated at the average experience gap rather than at zero. The models otherwise retain the specification used in the main analysis.

Table 7: Within-Team Experience Gap

	(1) Same Nationality	(2) Same Language	(3) Lang. Proximity
Culture (C) – mean gap	0.0356** (0.0164)	0.0447*** (0.0157)	0.0409*** (0.0157)
C × exp_gap_dm	0.0032 (0.0034)	0.0038 (0.0032)	0.0036 (0.0032)
exp_gap_dm (main)	−0.0036* (0.0021)	−0.0045* (0.0025)	−0.0045* (0.0025)
Controls (Table 3 set)	Yes	Yes	Yes
Tournament × year FE	Yes	Yes	Yes
Round FE	Yes	Yes	Yes
Pseudo- R^2	0.097	0.097	0.097
N	3,728	3,728	3,728

*** p<0.01, ** p<0.05, * p<0.10. Standard errors in parentheses, clustered by match. *exp_gap_dm* = $|\text{exp}_i - \text{exp}_j|$, demeaned at the sample mean (5.50 years, SD 4.92); individual tenure is imputed to 1 year for rookies. Controls include team-average *exp_mean_dm* and its square, plus *exp_gap_dm* itself. A robustness spec adding $C \times \text{exp_gap_dm}^2$ leaves the conclusion unchanged (quadratic term and linear term both insignificant throughout, $p > 0.29$).

The results provide no evidence that cultural similarity becomes more strongly associated with performance as the experience gap increases. The interaction is positive for all three measures—0.0032 for same nationality ($p=0.344$), 0.0038 for same language ($p=0.232$), and 0.0036 for linguistic proximity ($p=0.261$)—but none is statistically significant. Allowing for a quadratic relationship between the experience gap and cultural similarity produces the same conclusion: the quadratic interactions are small and statistically insignificant, while the linear interactions remain insignificant.

The results therefore distinguish the two potential mechanisms. We find evidence that the association between cultural similarity and performance becomes stronger among more experienced teams, particularly for language-related measures, but no evidence supporting the specific prediction that cultural similarity is especially valuable as a bridge across unequal experience levels. The findings are consequently more consistent with an interpretation based on accumulated professional experience and coordination.

This distinction is important for interpreting the mechanism. We do not find evidence that cultural similarity primarily helps an experienced player transmit knowledge to a less experienced teammate. Instead, the results point toward a setting in which the value of cultural and linguistic compatibility is greater among teams whose members have accumulated more professional experience. While this pattern is consistent with

the gradual development of shared expectations and coordination routines, the available data do not allow us to observe those processes directly.

6 Team Formation and Cultural Sorting

Partnership formation in professional doubles tennis is inherently multidimensional. Players may sort according to ability, experience, playing style, professional relationships, or commercial connections, among other considerations. We focus here on one dimension of this broader matching process: cultural similarity. An important feature of doubles tennis is that teams are formed bilaterally between players rather than assigned exogenously. This makes partnership formation relevant for interpreting the performance associations documented above. Békés and Ottaviano (2025) show that cultural similarity is systematically related to interaction patterns within professional football teams, demonstrating that culturally structured collaboration persists even among highly skilled professionals working in common organizational settings. Our data reveal a related pattern at the stage of team formation: players are substantially more likely to form partnerships with culturally similar teammates than would be expected under random matching. We therefore examine partnership formation separately from the performance analysis. The purpose of this section is not to eliminate selection concerns or to establish that partnerships are formed exogenously, but to document how cultural sorting operates in the doubles environment and whether it is particularly pronounced among stronger players. We first compare observed cultural similarity in partnerships with the corresponding random-matching benchmark, then examine whether a player’s own doubles ranking predicts the cultural similarity of their partner, and finally describe how partnership formation varies around the Olympic cycles. Together, these analyses provide a more transparent picture of the selection environment in which the performance associations arise.

6.1 Cultural Sorting in Partnership Formation

We construct a partnership-level sample containing each distinct men’s doubles partnership appearing in the Grand Slams between 2018 and 2025. A partnership is counted once within a tournament, even if the same pair advances through several rounds, be-

cause partner formation occurs before the subsequent match outcomes. The resulting sample contains 2,089 partnerships with complete ranking information (542 at the Australian Open, 543 at Roland Garros, 487 at Wimbledon, and 517 at the US Open; see Table 2, Panel B).

We compare the observed prevalence of cultural similarity with the rate expected under random matching within each tournament-year. The random-matching benchmark is calculated directly from the composition of the actual player field: for each tournament-year, we calculate the share of all possible player pairs that would satisfy the relevant cultural criterion. This produces a deterministic benchmark that accounts for the nationality and language composition of each tournament field.

Table 8: Cultural Sorting in Partnership Formation: Actual vs. Random-Matching Benchmark

Measure		All ranked players ($N=2,089$)	Both partners top-100 ($N=1,211$)	Both partners top-50 ($N=712$)
Same nationality	Actual	42.2%	32.6%	35.5%
	Random benchmark	5.2%	4.1%	4.5%
Same language	Actual	56.0%	49.7%	56.3%
	Random benchmark	16.2%	15.5%	15.8%
Mean ling. prox.	Actual	0.568	0.506	0.565
	Random benchmark	0.199	0.189	0.189

Note: one row per distinct partnership per tournament (2,089 partnerships, Grand Slams 2018–2025, Olympics excluded). Random benchmark is the closed-form expected rate under random pairing within each tournament-year’s actual field, using the same CEPII *comlang_off/comlang_ethno* country-pair lookup underlying *same.language/ling-prox*.

The results in Table 8 show substantial cultural sorting. Among all partnerships, 42.2% consist of players of the same nationality, compared with 5.2% under random matching. Similarly, 56.0% of partnerships share an official language, compared with 16.2% under random matching. Mean linguistic proximity is 0.568 among observed partnerships, compared with 0.199 under random matching. Thus, doubles partnerships are strongly assortative along all three dimensions of cultural similarity.

This finding is important for interpreting the performance results. Cultural similarity is clearly not randomly distributed across partnerships: players who form teams are much more culturally similar than would be expected from the composition of the tournament field alone. The match-performance estimates should therefore not be in-

terpreted as if cultural similarity were randomly assigned. Rather, they describe an association between the cultural composition of an already formed partnership and its subsequent performance.

At the same time, the sorting does not appear to be concentrated among the strongest players. Among partnerships in which both players are ranked in the top 100, 32.6% are same-nationality partnerships, compared with 4.1% under random matching. Among partnerships with both players in the top 50, the corresponding figures are 35.5% and 4.5%. The corresponding actual-to-random ratios are therefore remarkably similar across groups. The same pattern is evident for shared language and linguistic proximity. Indeed, the raw prevalence of same-nationality partnerships is lower among top-50 and top-100 partnerships than in the full sample, while same-language sorting remains broadly similar.

These comparisons provide no evidence that the cultural sorting observed in doubles is disproportionately driven by the strongest players.

6.2 Player Ranking and Partner Selection

We next examine the relationship between a player’s own ranking and the cultural similarity of the partnership more directly. For each partnership, we treat each player in turn as the focal player, generating two player-level observations per partnership. This produces 4,178 player-partnership observations from the 2,089 partnerships. Because the same partnership contributes two observations, standard errors are clustered at the partnership level.

We regress each cultural-similarity measure on the focal player’s own doubles ranking, including tournament-by-year fixed effects. [Because the cultural composition of the player pool differs across tournament-years, a player’s probability of having a culturally similar partner may vary mechanically with the set of players entering the event. We therefore extend the specification to also account for the cultural composition of the tournament field: for each focal player, the share of every *other* player in that tournament-year’s full field \(every entrant, not only the rank-complete partnerships used above\) who shares the focal player’s nationality – and, analogously, the mean pairwise value of *same_language/ling_prox* against every other player in the field – matched to](#)

the corresponding outcome. The specification is deliberately parsimonious: the purpose is not to explain partner selection comprehensively, but to test whether a player’s own ranking predicts the cultural similarity of the partner within a given tournament-year, and whether that association survives controlling for field composition.

The results are reported in Table 9. In Spec 1 (own ranking alone), the coefficient on own ranking is positive and statistically significant for all three measures: 0.000269 for same nationality ($p < 0.001$), 0.000146 for same language ($p = 0.012$), and 0.000139 for linguistic proximity ($p = 0.009$). Because a lower doubles-ranking number indicates a stronger player, the positive coefficient means that worse-ranked players are, if anything, more likely to have culturally similar partners.

We estimate three specifications: (1) own ranking alone (as above); (2) the outcome-matched field-composition variable alone; and (3) own ranking plus field composition. All three specifications exclude the 3 ego-rows whose own nationality is represented by exactly one player in the ego-row sample, so that a single lone-nationality observation cannot by itself drive any coefficient; this leaves $N = 4,175$ (from 4,178) throughout. We also estimated an own-nationality (country fixed effects) specification in place of own ranking, but do not report it: nationality is a 60-level categorical variable, so it produces 59 separate country-dummy coefficients rather than one interpretable effect, and its logit specifications fail to converge for the two binary outcomes regardless (quasi-complete separation, since several nationalities have as few as 2 ego-rows).

Field composition alone (Spec 2) is also a strong, highly significant predictor of all three outcomes, as expected – a player drawn from a tournament field with more compatriots or linguistically similar entrants is mechanically more likely to end up with a culturally similar partner. Adding both own ranking and field composition together (Spec 3) shrinks the own-ranking coefficients by roughly half relative to Spec 1 but leaves them positive and statistically significant for all three outcomes ($p < 0.05$ throughout), while the composition coefficient stays close to its Spec 2 magnitude. Own ranking therefore predicts partner similarity *in addition to*, not merely *because of*, the cultural composition of the field a player happens to be drawn from.

This result is the opposite of what would be expected if the performance association were primarily generated by stronger players having greater partner choice and

Table 9: Own Ranking, Tournament-Field Composition, and Partner-Culture Similarity

Outcome	Spec 1: own_rank	Spec 2: composition	Spec 3: own_rank	Spec 3: composition
Same nationality (AME)	0.000269*** (0.000056)	3.853*** (0.241325)	0.000116** (0.000053)	3.756*** (0.255403)
Same language (AME)	0.000146** (0.000058)	1.275*** (0.081709)	0.000117** (0.000053)	1.267*** (0.082578)
Ling. proximity (OLS coef.)	0.000139*** (0.000053)	1.152*** (0.075655)	0.000104** (0.000047)	1.145*** (0.076295)
N (ego-rows)	4,175	4,175	4,175	4,175

*** $p < 0.01$, ** $p < 0.05$, * $p < 0.10$. Standard errors in parentheses, clustered by partnership. All specifications include tournament $\times$ year FE and exclude ego-rows whose own nationality has exactly 1 observation in the ego-row sample (3 rows dropped; $N = 4,175$, from 4,178). Field composition is ($\#$ other field entrants sharing the focal player's nationality)/(field size -1) for same nationality, and the analogous mean pairwise value for same language / linguistic proximity, computed against every other player entering that tournament-year (not only the rank-complete partnerships in the estimation sample).

systematically selecting culturally similar teammates. Together with the bracket comparisons, the evidence therefore provides no support for the specific selection mechanism in which stronger players disproportionately sort into culturally similar partnerships. It does not, however, eliminate other forms of endogenous partnership formation, and the performance estimates remain associations rather than causal effects.

6.3 Team Formation Around the Olympic Cycle

The regular professional doubles circuit provides a setting in which players have substantial discretion over their partners, while Olympic doubles imposes a distinct institutional constraint: teams must represent the same nation. This raises a broader question about how institutional constraints interact with decentralized partnership formation. The Olympic requirement could, in principle, also increase the salience of national affiliation in the regular professional circuit, particularly as the Games approach, potentially generating spillovers in the cultural composition of Grand Slam partnerships.

Finally, we provide a descriptive perspective on partnership formation by examining whether cultural sorting changes around the Olympic Games. The Olympic Games provide a separate setting in which the incentives surrounding partner formation are particularly salient. Unlike Grand Slam doubles competition, Olympic participation is

organized around national representation, creating a direct incentive for players seeking to compete together at the Games to form partnerships with compatriots. We therefore examine whether the composition of Grand Slam partnerships changes during the preparation periods surrounding the Tokyo 2021 and Paris 2024 Olympic Games. The analysis is descriptive and is intended to provide additional evidence on how partnership formation responds to the institutional environment surrounding elite competition.

For the Tokyo cycle, we divide the Grand Slam sample into three periods: a pre-Tokyo period covering the Australian Open 2018 through the US Open 2019; a Tokyo preparation period covering the Australian Open 2020 through Wimbledon 2021, excluding the cancelled 2020 Wimbledon; and a post-Tokyo period covering the US Open 2021 through the US Open 2022. For the Paris cycle, the pre-Paris period covers the 2022 Grand Slams, the Paris preparation period covers the Australian Open 2023 through Wimbledon 2024, and the post-Paris period covers the US Open 2024 through the US Open 2025.

Table 10: Grand Slam Partnerships Around the Tokyo 2021 and Paris 2024 Olympic Cycles

Measure	Tokyo 2021 cycle			Paris 2024 cycle		
	Pre-Tokyo	Tokyo Prep	Post-Tokyo	Pre-Paris	Paris Prep	Post-Paris
Same nationality	40.0%	40.3%	39.0%	39.3%	42.6%	43.9%
Same language	54.8%	55.0%	54.8%	54.1%	57.6%	58.8%
Ling. proximity (mean)	0.557	0.551	0.556	0.552	0.580	0.602
<i>N</i>	980	680	602	484	860	626

Note: Olympics excluded throughout. Windows: Pre-Tokyo = Jan 2018–Dec 2019; Tokyo Prep = Jan 2020–Jul 2021 (excludes Wimbledon 2020, cancelled); Post-Tokyo = Aug 2021–Dec 2022; Pre-Paris = Jan–Dec 2022; Paris Prep = Jan 2023–Jul 2024; Post-Paris = Aug 2024–Dec 2025.

The share of same-nationality teams is remarkably stable across the Tokyo cycle’s three periods, at 40.0%, 40.3%, and 39.0%, respectively (Table 10). The corresponding shares for shared official language are 54.8%, 55.0%, and 54.8%, while mean linguistic proximity is 0.557, 0.551, and 0.556.

The absence of an increase during the Tokyo preparation period is noteworthy because the Tokyo cycle took place during the COVID-19 pandemic. International travel and cross-border interaction were unusually difficult during this period, potentially increasing the relative attractiveness of partnering with compatriots or players from nearby

linguistic communities. Nevertheless, the descriptive composition of teams does not show an increase in same-nationality or language-based partnerships during the preparation period.

Figure 1: Share of Grand Slam doubles teams sharing a nationality, 2018–2025, spanning both the Tokyo 2021 and Paris 2024 Olympic cycles. Shaded bands mark the pre/preparation/post periods used in Table 10; dashed vertical lines mark the Games themselves.

The Paris cycle provides a contrasting pattern (Table 10 and Figure 1). Same-nationality partnerships account for 39.3% of teams before the Paris Games, 42.6% during the preparation period, and 43.9% afterwards. Shared-language partnerships increase from 54.1% to 57.6% and then 58.8%, while mean linguistic proximity rises from 0.552 to 0.580 and then 0.602.

The contrast between the two Olympic cycles should not be interpreted as a causal estimate of Olympic incentives on partner formation. The two periods differ in many dimensions, most importantly the extraordinary conditions surrounding the Tokyo Games. Instead, the descriptive evidence illustrates that the composition of doubles partnerships can vary with the broader institutional and competitive environment. It also reinforces the broader conclusion from this section: partnership formation involves substantial cultural sorting, but that sorting is not simply a consequence of the strongest players systematically selecting culturally similar teammates.

This evidence should be interpreted cautiously. The Olympics involve a small and highly selected set of players, and their qualification rules differ substantially from those governing the Grand Slam circuit. Moreover, the timing and strength of any spillover from Olympic participation or national representation to regular partnership decisions

are not clear. Players may also respond to Olympic considerations in lower-level tournaments or through partnership decisions that are not captured by changes in the aggregate Grand Slam composition. We therefore do not interpret the stable pattern as evidence that the Olympic institution has no effect on partnership formation. Rather, it provides descriptive evidence that the heightened salience of national representation around the Olympics is not accompanied by a large, readily visible change in the cultural composition of the broader Grand Slam partnership market.

Overall, the evidence in this section provides useful context for interpreting the main performance results. Cultural sorting is clearly present, but the data do not support the specific hypothesis that stronger players are disproportionately responsible for that sorting. At the same time, partnerships are formed through a mixture of deliberate choice and circumstances that can constrain partner selection. We therefore do not interpret the main estimates as causal effects of cultural similarity. Rather, the team-formation evidence helps assess the plausibility of one important alternative explanation for the observed association between cultural similarity and team performance.

7 Conclusion

Attention: tennis doubles are formed by individual players, not by a manager or an organization. Different implications if were assigned by managers/organizations like football. The findings also have implications for organizations in which employees have discretion over their collaborators. In such settings, team composition may emerge partly through endogenous cultural sorting rather than solely through managerial assignment. If cultural similarity facilitates coordination, such sorting may reflect an economically meaningful feature of decentralized team formation. At the same time, our results do not imply that managers should systematically favor culturally similar teams: the evidence is observational, and culturally homogeneous partnerships may also reflect selection into partnerships on unobserved characteristics.

Cultural diversity is increasingly a feature of how organizations assemble teams, but the organizational value of diversity depends not only on what individuals bring to a team but also on how effectively they can combine those resources. Our findings suggests that cultural similarity is associated with better team performance, but that this asso-

ciation is neither universal nor mechanical. Its relevance appears to depend on whether teammates have sufficient opportunity to communicate, develop shared understandings, and translate those understandings into coordinated action.

This perspective complements the recent finding that cultural homophily shapes collaboration even among highly skilled professionals in multinational football teams (Békés and Ottaviano, 2025). Their evidence shows that cultural similarity affects how teammates interact; our evidence suggests that such differences in interaction can also be reflected in collective performance. The distinction is important for management research. If cultural similarity matters partly because it lowers coordination costs, then its organizational consequences should depend on the structure of the task. Teams performing highly interdependent work, working under substantial time pressure, or relying on repeated interaction may be particularly sensitive to these costs. Conversely, organizations may be able to capture the informational benefits of cultural diversity when tasks allow greater time for communication, clearer division of responsibilities, or other mechanisms that reduce the need for implicit coordination.

[The performance relevance of cultural similarity depends on whether the structure of the task allows communication and coordination advantages to accumulate.](#)

The findings also suggest a more nuanced view of team composition. A natural managerial response to evidence of coordination costs would be to favor culturally similar employees when assembling teams. Our results do not justify such a prescription. Cultural similarity is strongly associated with partnership formation, but the evidence does not indicate that the strongest players are disproportionately responsible for this sorting. More importantly, our analysis is observational and cannot establish that cultural similarity itself causes superior performance. Cultural similarity may proxy for other dimensions of compatibility, partnership history, social networks, or unobserved characteristics that influence both team formation and performance. The evidence on experience is consistent with a role for accumulated shared experience, but it does not identify the precise process through which communication advantages develop.

[Cultural similarity may be more valuable when teams perform tasks requiring repeated interdependent coordination, communication, and adaptation. The value may be less visible when tasks are sufficiently short, tightly constrained, or dominated by](#)

small differences in performance. Managers should think about cultural composition jointly with task structure, rather than treating cultural similarity as inherently good or bad. Our evidence suggests that its performance relevance depends on whether team members have sufficient opportunity to communicate, adjust, and coordinate their actions over the course of a task.

These limitations point toward an important agenda for future research. The central challenge is to move from observing cultural similarity to identifying the coordination process through which similarity affects team production. Experimental or quasi-experimental variation in team composition could help separate cultural compatibility from selection into partnerships. Richer longitudinal data could distinguish shared experience with a particular teammate from general professional experience and examine whether coordination routines develop through repeated interaction. Direct measures of communication—such as verbal exchanges, shared decision-making, or behavioral measures of anticipation—could provide an even more direct test of whether cultural and linguistic similarity operate through communication costs and shared mental models.

More broadly, the paper suggests that the consequences of diversity should be understood as a property of the interaction between team composition and task design, rather than as an inherent feature of diversity itself. Cultural differences may provide organizations with access to heterogeneous knowledge, perspectives, and networks, while simultaneously increasing the effort required to integrate those resources. Whether the balance is favorable depends on the extent to which an organization's production process relies on rapid, repeated, and interdependent coordination. Understanding this interaction is important for managers designing teams, but also for economists and organizational scholars seeking to explain when diversity becomes an asset, when it becomes a coordination challenge, and how organizations can reduce the costs of bringing different people together.
